## Data Analysis \& Student t Test

Probably the most common test used in data analysis is the Student t test: this test is a test of the mean. With it, you can determine the $90 \%$ confidence interval for

- The gain of a transistor,
- The energy in a AA battery,
- The value of a capacitor, or
- The thermal time constant of a coffee cup.

You can also compare two populations and determine

- Does type A battery have more energy than type B?
- Does adding a spoon to a cup of hot water make it cool off faster?
- Does adding a lid help keep it warm?

The heart of the Student t -Test is the standard normal distribution. This is the bell-shaped curve you've encounter many times (grade distribution, sum of rolling 10 dice, height of people, etc.) When doing a t-test, you're implicitly assuming that the data you're analyzing has a normal distribution.

This actually isn't that bad of an assumption. The Central Limit Theorem states that, under some very general assumptions,

- The sum or average of random variables converges to a normal distribution, and
- The sum of normal distributions is a normal distribution.

Translating: everything converges to a normal distribution. Once you get there, you're stuck with a normal distribution.

This lecture covers how to analyze data like we collected before.

## Student t-Test

The Student-t distribution is described by three parameters: the mean, standard deviation, and degrees of freedom

Mean: The average of your data

$$
\bar{x}=\frac{1}{n} \sum x_{i}
$$

Standard Deviation: A measure of the spread

$$
s=\sqrt{\frac{1}{n-1} \sum\left(x_{i}-\bar{x}\right)^{2}}
$$

Degrees of Freedom: Sample size minus one
d.f. = n-1

The probability density function is very similar to a normal distribution, only the tails are slightly extended in accordance to the sample size. As the sample size goes to infinity, the t-distribution converges to the normal distribution

$$
p(x)=\frac{1}{\sqrt{2 \pi s}} \exp \left(\frac{-(x-\bar{x})^{2}}{2 s^{2}}\right)
$$

The probability of getting a value is related to how far you are from the mean in terms of standard deviations, termed the $t$-score

$$
t=\frac{x-\bar{x}}{s}
$$

It's probably easiest to explain this through an example.

## Example 1: Gain of a Zetex Transistor

The gain of a Zetex 1051a transistor was measured resulting in the following data:

```
915, 602, 963, 839, 815, 774, 881, 912, 720, 707, 800, 1050, 663, 1066, 1073,
802, 863, 845, 789, 964, 988, 781, 776, 869, 899, 1093, 1015, 751, 795, 776, 860,
990, 762, 975, 918, 1080, 774, 932, 717, 1168, 912, 833, 697, 797, 818, 891, 725,
662, 718, 728, 835, 882, 783, 784, 737, 822, 918, 906, 1010, 819, 955, 762
```

## Determine

- Probability density function for any given Zetex 1051a transistor
- The probability that the gain for any given Zetex 1051a transistor being more than 500
- The $90 \%$ confidence interval for any given Zetex 1051a transistor, and

Solution: First, determine the mean, standard deviation, and sample size. In Matlab

```
hfe = [ <paste data here> ]
x = mean(hfe)
x = 854.1290
s = std(hfe)
s=120.2034
df = length(hfe) - 1
df = 61
```

You can now plot the probability density function by starting with a standard normal distribution (mean $=0$, standard deviation $=1$ ) and scaling it

```
x1 = [-4:0.05:4]';
p = exp(-x1.^2 / 2);
plot(x1*s+x, p);
```

Normalize probability density function for a Zetex 1051a transistor

With this, you can now answer several questions.
i) What is the probability density function for any given Zetex 1051a transistor? answer: The graph above.
ii) What is the probability that the gain of any given Zetex transistor is more than 500 ?
answer: This is the are to the right of 500 . First, compute the t -score (the distance from the mean in terms of standard deviations)

$$
t=\left(\frac{500-\bar{x}}{s}\right)=\left(\frac{500-854.129}{120.2}\right)=-2.9461
$$

The t -score is the distance from the mean in terms of standard deviations

To convert this t-score to a probability, use a t -table.
To use a t-table,

- Go to the row with 61 degrees of freedom (which isn't on the table so use 60 )
- Look for the number 2.9461 (the sign doesn't matter)
- The top of the table tells you the area of the tail

The area of the tail is about 0.002 (?)
The probability that the gain is less than $\mathbf{5 0 0}$ is $\mathbf{0 . 0 0 2 3}$
The probability that the gain is more than $\mathbf{5 0 0}$ is $\mathbf{0 . 9 9 7 7}$

| Student t-Table (area of tail) |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| p | 0.25 | 0.20 | 0.15 | 0.10 | 0.05 | 0.025 | 0.01 | 0.005 | 0.001 | 0.0005 |  |  |  |  |  |  |  |  |
| 1 | 1 | 1.38 | 1.96 | 3.08 | 6.31 | 12.71 | 31.82 | 63.66 | 318.31 | 636.62 |  |  |  |  |  |  |  |  |
| 2 | 0.82 | 1.06 | 1.39 | 1.89 | 2.92 | 4.3 | 6.97 | 9.93 | 22.33 | 31.6 |  |  |  |  |  |  |  |  |
| 3 | 0.77 | 0.98 | 1.25 | 1.64 | 2.35 | 3.18 | 4.54 | 5.84 | 10.22 | 12.92 |  |  |  |  |  |  |  |  |
| 4 | 0.74 | 0.94 | 1.19 | 1.53 | 2.13 | 2.78 | 3.75 | 4.6 | 7.17 | 8.61 |  |  |  |  |  |  |  |  |
| 5 | 0.73 | 0.92 | 1.16 | 1.48 | 2.02 | 2.57 | 3.37 | 4.03 | 5.89 | 6.87 |  |  |  |  |  |  |  |  |
| 10 | 0.7 | 0.88 | 1.09 | 1.37 | 1.81 | 2.23 | 2.76 | 3.17 | 4.14 | 4.59 |  |  |  |  |  |  |  |  |
| 15 | 0.69 | 0.87 | 1.07 | 1.34 | 1.75 | 2.13 | 2.6 | 2.95 | 3.73 | 4.07 |  |  |  |  |  |  |  |  |
| 20 | 0.69 | 0.86 | 1.06 | 1.33 | 1.73 | 2.09 | 2.53 | 2.85 | 3.55 | 3.85 |  |  |  |  |  |  |  |  |
| 60 | 0.68 | 0.848 | 1.05 | 1.3 | 1.67 | 2 | 2.390 | 2.660 | 3.232 | 3.46 |  |  |  |  |  |  |  |  |
| infinity | 0.674 | 0.842 | 1.036 | 1.282 | 1.645 | 1.960 | 2.326 | 2.576 | 3.090 | 3.29 |  |  |  |  |  |  |  |  |

Another (easier) way to do this is to go to StatTrek. The area of the tail is 0.0023

www.StatTrek.com

The probability that any given Zetex 1051a transistor has a gain more than 500 is 0.9977
iii) What is the $90 \%$ confidence interval for the gain of a Zetex 1051a transistor?
answer: For $90 \%$ of the area to be in the middle, each tail needs to be $5 \%$. From the $t$-table, this corresponds to

$$
\mathrm{t}=1.67
$$

The $90 \%$ confidence integral is thus

$$
\bar{x}-1.67 s<\text { gain }<\bar{x}+1.67 s
$$

$653<$ gain $<1055$

$90 \%$ confidence interval for the gain of a Zetex 1051a transistor
"If you don't know where you are going any road can take you there"
Lewis Carroll, Alice in Wonderland

## Design of Experiment

Suppose you want to know
How much energy does a AA battery contain?
Before starting, think about how you will answer this question: ask the following:

- What question you want to answer?
- What data you need to answer that question?
- How much data you need?
- How you will go about collecting that data?
- How you will analyze that data?

The point behind this is to

- Collect the right data (don't waste time collecting data you can't use)
- Collect the right amount of data (don't waste time collecting too much or too little data)
- Make the experiment as repeatable as possible (minimize the variation in the data)

## Example 2: Energy in a AA battery

Suppose you want to know
How much energy does a AA battery contain?

## What data do we need?

Energy is hard to measure, Voltage is easy. If you

- Short the battery across a 10 Ohm resistor, and
- Measure the voltage every 6 seconds,

You can measure the power being dissipated in Watts

$$
P=\frac{V^{2}}{R}=0.1 V^{2} \quad \text { Watts }
$$

If you let the experiment run until the battery is discharged, you'll have the energy in Joules

$$
E=\int P d t \quad \text { Joules }
$$

## How Much Data do you Need?

This is where t-tables are kind of insightful.

- One data point (discharging one battery) tells you nothing. One battery has zero degrees of freedom
- Two data points actually let you analyze the data and answer your questions
- If you can afford to test three batteries, the $t$-score drops drastically (see the column for 0.01 : the $t$-score drops from 31.82 to 6.97 by going from 1 to 2 degrees of freedom)
- You start to get diminishing returns once you go past 10

| Student t -Table (area of tail) |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| p | 0.25 | 0.20 | 0.15 | 0.10 | 0.05 | 0.025 | 0.01 | 0.005 | 0.001 | 0.0005 |  |  |  |  |  |  |
| 1 | 1 | 1.38 | 1.96 | 3.08 | 6.31 | 12.71 | 31.82 | 63.66 | 318.31 | 636.62 |  |  |  |  |  |  |
| 2 | 0.82 | 1.06 | 1.39 | 1.89 | 2.92 | 4.3 | 6.97 | 9.93 | 22.33 | 31.6 |  |  |  |  |  |  |
| 3 | 0.77 | 0.98 | 1.25 | 1.64 | 2.35 | 3.18 | 4.54 | 5.84 | 10.22 | 12.92 |  |  |  |  |  |  |
| 4 | 0.74 | 0.94 | 1.19 | 1.53 | 2.13 | 2.78 | 3.75 | 4.6 | 7.17 | 8.61 |  |  |  |  |  |  |
| 5 | 0.73 | 0.92 | 1.16 | 1.48 | 2.02 | 2.57 | 3.37 | 4.03 | 5.89 | 6.87 |  |  |  |  |  |  |
| 10 | 0.7 | 0.88 | 1.09 | 1.37 | 1.81 | 2.23 | 2.76 | 3.17 | 4.14 | 4.59 |  |  |  |  |  |  |
| 15 | 0.69 | 0.87 | 1.07 | 1.34 | 1.75 | 2.13 | 2.6 | 2.95 | 3.73 | 4.07 |  |  |  |  |  |  |
| 20 | 0.69 | 0.86 | 1.06 | 1.33 | 1.73 | 2.09 | 2.53 | 2.85 | 3.55 | 3.85 |  |  |  |  |  |  |
| 60 | 0.68 | 0.848 | 1.05 | 1.3 | 1.67 | 2 | 2.390 | 2.660 | 3.232 | 3.46 |  |  |  |  |  |  |
| infinity | 0.674 | 0.842 | 1.036 | 1.282 | 1.645 | 1.960 | 2.326 | 2.576 | 3.090 | 3.29 |  |  |  |  |  |  |

This is important. In industry, you typically have to scrap every item you test: it's no longer new.

- If you test all of your products, you have good data for statistical analysis. You're also broke since you no longer have any product to sell.
- If you test none of your products, you have no idea what you're selling.
- All you really need is a sample size of two. You can do statistical analysis with a sample size of two.
- Given a choice, a sample size of 4 or 5 would be nice. That gives you a lot more information and you only lose 4 or 5 from your inventory. These you can probably sell on ebay as "like new."

Long story short, let's test four batteries (for 3 degrees of freedom)

## How will you collect that data?

This is where you get really picky about the experimental procedure. The goal is to follow a set procedure precisely. The hope is that if you do everything the same each time you run the experiment, you'll get the same data.

If you don't follow a procedure and are sloppy in collecting data, you tend to get wildly varying results (which shows up as a large standard deviation). If you have a large standard deviation, you'll end up saying something like

I am 90\% certain that the energy in a AA battery is in the range of (-2000 Joules to $+20,000$ Joules)
A not terribly helpful conclusion.

For this experiment, the procedure was

- Purchase a pack of 4 batteries from the grocery store
- Connect a 10 Ohm resistor across each battery
- Measure the voltage across each battery using a PIC processor, sampled every 6 seconds
- Run the experiment for each battery for 10 hours.

## Step 2: Data Collection

Once you have the procedure, collect data. The result is as follows:

Voltage across four AA batteries as they discharge across a 10 Ohm resistor

## Step 3: Data Analysis

In order to analyze the data, you need to convert each data set to a number.

- The average of the data is a number. It doesn't tell me much though.
- The time it takes to discharge down to 1.00 V is a number. It sort of tells me the life of a battery.
- The energy contained in the battery in Joules is a number. That's actually useful information.

So, convert each graph to the energy contained in Joules.

The power dissipated is

$$
P=\frac{V^{2}}{R}=0.1 V^{2} \text { Watts }
$$

The energy is the integral of the power. Since the sampling rate is 6 seconds

$$
E=0.6 \sum\left(V^{2}\right)
$$

giving four numbers (one for each data set)

$$
E=\left\{\begin{array}{llll}
26,332 & 26,648 & 27,330 & 26,543
\end{array}\right\} \text { Joules }
$$

Now that you have four numbers, you can do some statistical analysis.

The mean is

```
x = mean(Joules)
x = 26,713
s = std(Joules)
s = 431.6950
```

The normalized probability of the energy in a given AA battery is thus

Energy in a AA battery: Mean $=26,713$, standard deviation $=431$ Joules

With this, you can answer some questions.

Question 1) What is the probability that a given batter will have more than $\mathbf{2 8 , 0 0 0}$ Joules?
To answer this, determine the distance from mean to 28,000 in terms of standard deviations.

$$
t=\left(\frac{28,000-\bar{x}}{s}\right)=\left(\frac{28,000-26,713}{431.69}\right)=2.9808
$$

Use a t-table to convert this to a probability

- In the dropdown box, describe the random variable.
- Enter a value for degrees of freedom.
- Enter a value for all but one of the remaining text boxes.
- Click the Calculate button to compute a value for the blank text box.

With a sample size of four, there are three degrees of freedom

- The probability that the energy is less than 28,000 is $97.07 \%$
- The probability that the energy is more than 28,000 is $2.93 \%$

## Question 2: What is the $\mathbf{9 0 \%}$ confidence interval for any given AA battery?

Answer: Use a t-table to convert $5 \%$ tails to at-score

The $90 \%$ confidence interval will be

$$
\bar{x}-2.355 s<\text { Joules }<\bar{x}+2.355 s
$$

25,6897 < Joules < 27,730

## Comparison of Means

Suppose you collect data from two populations, A and B. What is the probability that the mean of A is more than the mean of $B$ ?

This is a common problem

- For batteries, you might want to know which one has more energy
- For coffee cups, you might want to know which one has better insulation

To solve this problem, create a new variable, W

$$
\mathrm{W}=\mathrm{A}-\mathrm{B}
$$

The mean and variance of W will be

$$
\begin{aligned}
& \bar{x}_{w}=\bar{x}_{a}-\bar{x}_{b} \\
& s_{w}^{2}=\frac{s_{a}^{2}}{n_{a}}+\frac{s_{b}^{2}}{n_{b}}
\end{aligned}
$$

The degrees of freedom is a little more tricky. It's equation is

$$
\text { d.f. }=\frac{\left(\left(\frac{s_{1}^{2}}{n_{1}}\right)+\left(\frac{s_{2}^{2}}{n_{2}}\right)\right)}{\left(\frac{\left(s_{1}^{2} / n_{1}\right)}{n_{1}-1}\right)+\left(\frac{\left(s_{2}^{2} / n_{2}\right)}{n_{2}-1}\right)}
$$

or, to be slightly conservative, it's the smaller of the degrees of freedom between A and B.

The probability that the mean of A is more than the mean of B is the probability that $\mathrm{W}>0$. This has a t -score of

$$
t=\frac{\bar{x}_{w}}{s_{w}}
$$

## Example 3: Which battery has more energy:

- $A=\{29,376 \quad 30,639 \quad 32,048 \quad 30,200\}$ Joules
- $B=\{30,18630,19730,668 \quad 29,820\}$ Joules

Solution: Create a new variable, $\mathrm{W}=\mathrm{A}-\mathrm{B}$. The mean and standard deviation are then:

|  | A | B | $\mathrm{W}=\mathrm{A}-\mathrm{B}$ |
| :---: | :---: | :---: | :---: |
| mean | 30,566 | 30,218 | 34.811 |
| st dev | 111.86 | 34.76 | 58.56 |
| d.f. | 3 | 3 | 3 |

Normalized probability distribution of type A and type B batteries

Probability distributions for Type-A batteries and Type-B batteries

The t-score is then the distance between the means relative to their standard deviations:

$$
t=\frac{\bar{x}_{a}-\bar{x}_{b}}{\sqrt{\frac{s_{a}^{2}}{n_{a}}+\frac{s_{b}^{2}}{n_{b}}}}=\frac{\bar{x}_{w}}{s_{w}}=\frac{34.811}{56.56}=0.5944
$$

From StatTrek, this corresponds to a probability of 0.7030

StatTrek: There is a $70.30 \%$ chance that battery A has more energy than battery B.
Matlab Code

```
A = [llllll}29376 30639 32048 30200]; 
B =[ [\begin{array}{llll}{30186 30197 30668 29820];}\end{array}]
Xa = mean(A)
Xa = 30566
Xb = mean(B)
Xb}=3021
Xw = Xa - Xb
Xw = 34.8110
Sa = std(A)
Sa = 111.8574
Sb = std(B)
Sb}=34.762
Sw = sqrt( Sa^2 / 4 + Sb^2 / 4 )
Sw = 58.5673
df = (Sa^2/4 + Sb^2/4) / (Sa^2/4/3 + Sb^2/4/3 )
df = 3
```
